Experiment no:-3

AIM: Observe and note the details of the live type of traffic (ARP, Frame analysis, ethernet) from interface using packet capture and analysis tool

REQUIREMENT:

WINDOWS 10 with LAN Connectivity.

Software: Cisco Packet Tracer

Theory:

We want to observe the ARP protocol in action. ARP is used to find the Ethernet address that corresponds to a local IP address to which your computer wants to send a packet. A typical example of a local IP address is that of the local router or default gateway that connects your computer to the rest of the Internet. Your computer caches these translations in an ARP cache so that the ARP protocol need only be used occasionally to do the translation. The setup from the viewpoint of your computer is as shown in the example below.

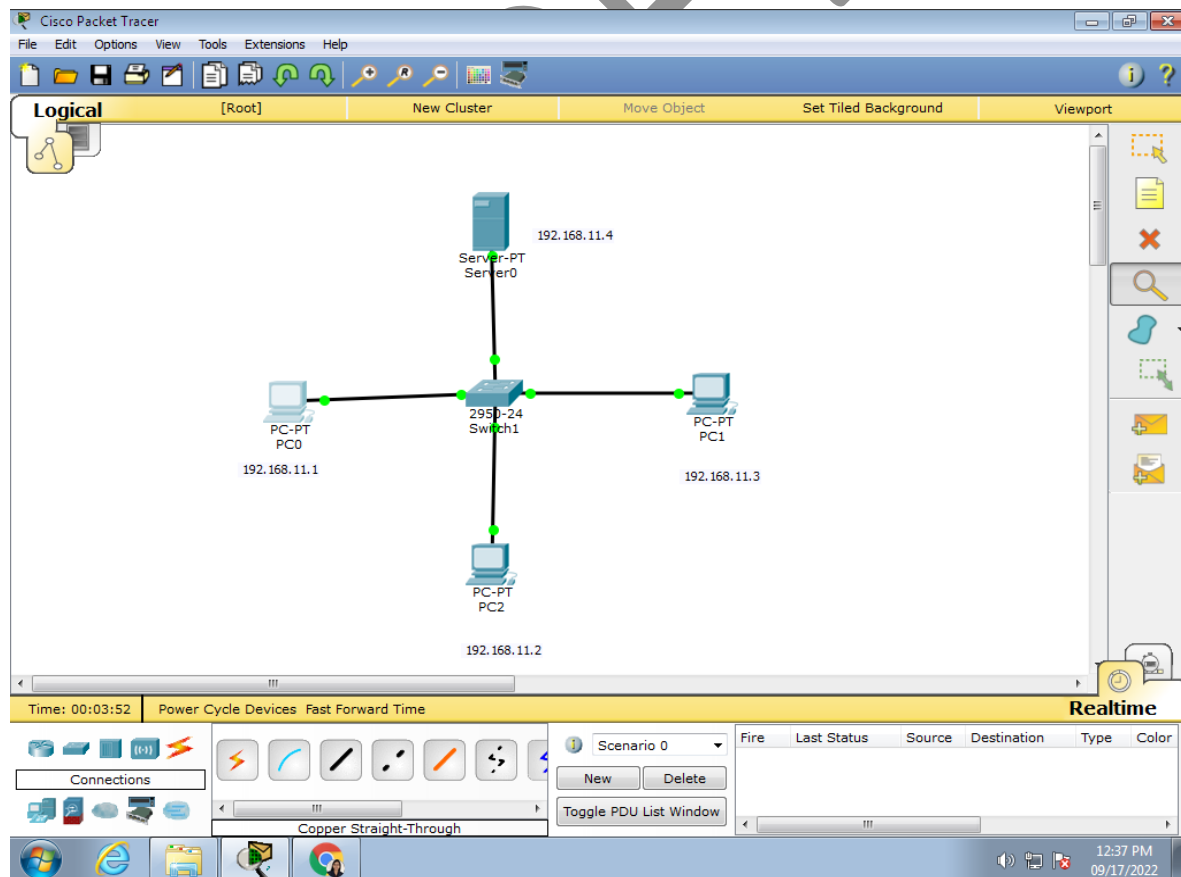

How ARP Works

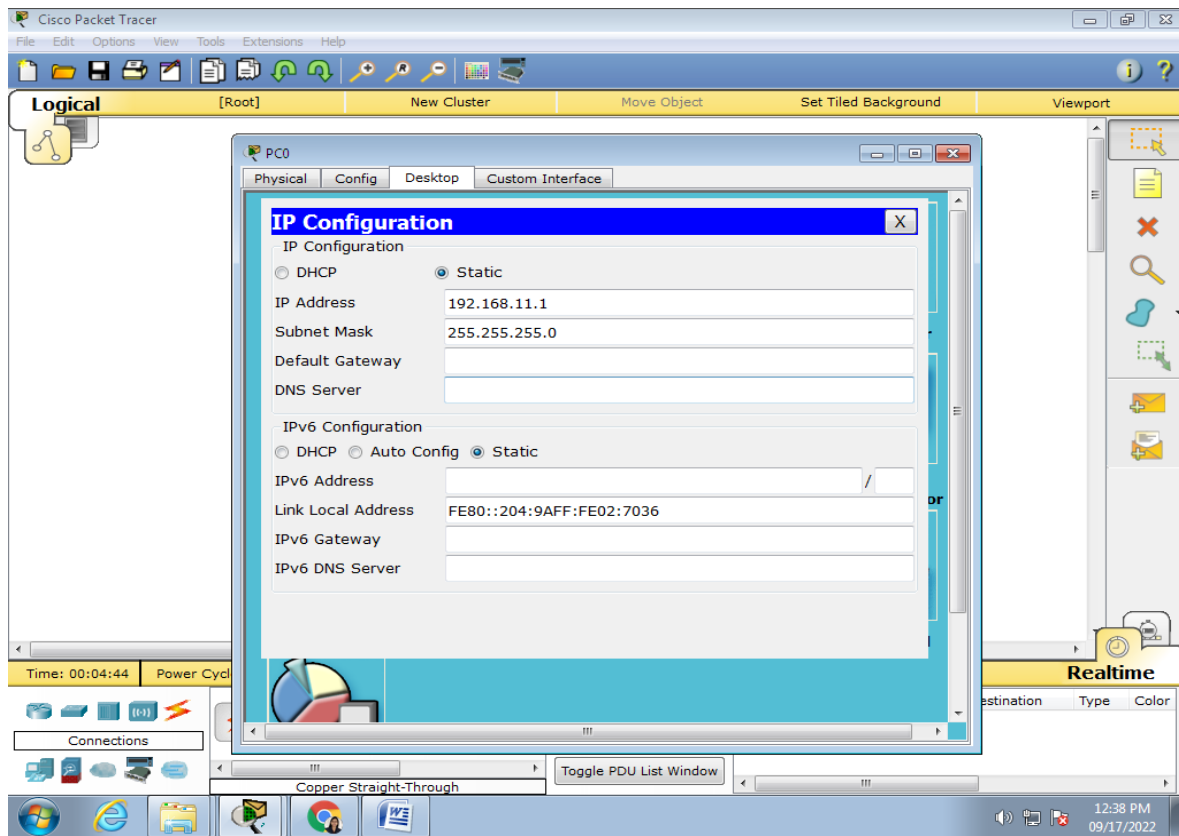

When an incoming packet destined for a host machine on a particular local area network arrives at a gateway, the gateway asks the ARP program to find a physical host or MAC address that matches the IP address. The ARP program looks in the

ARP cache and, if it finds the address, provides it so that the packet can be converted to the right packet length and format and sent to the machine. If no entry is found for the IP address, ARP broadcasts a request packet in a special format to all the machines on the LAN to see if one machine knows that it has that IP address associated with it. A machine that recognizes the IP address as its own returns a reply so indicating. ARP updates the ARP cache for future reference and then sends the packet to the MAC address that replied.

Steps:

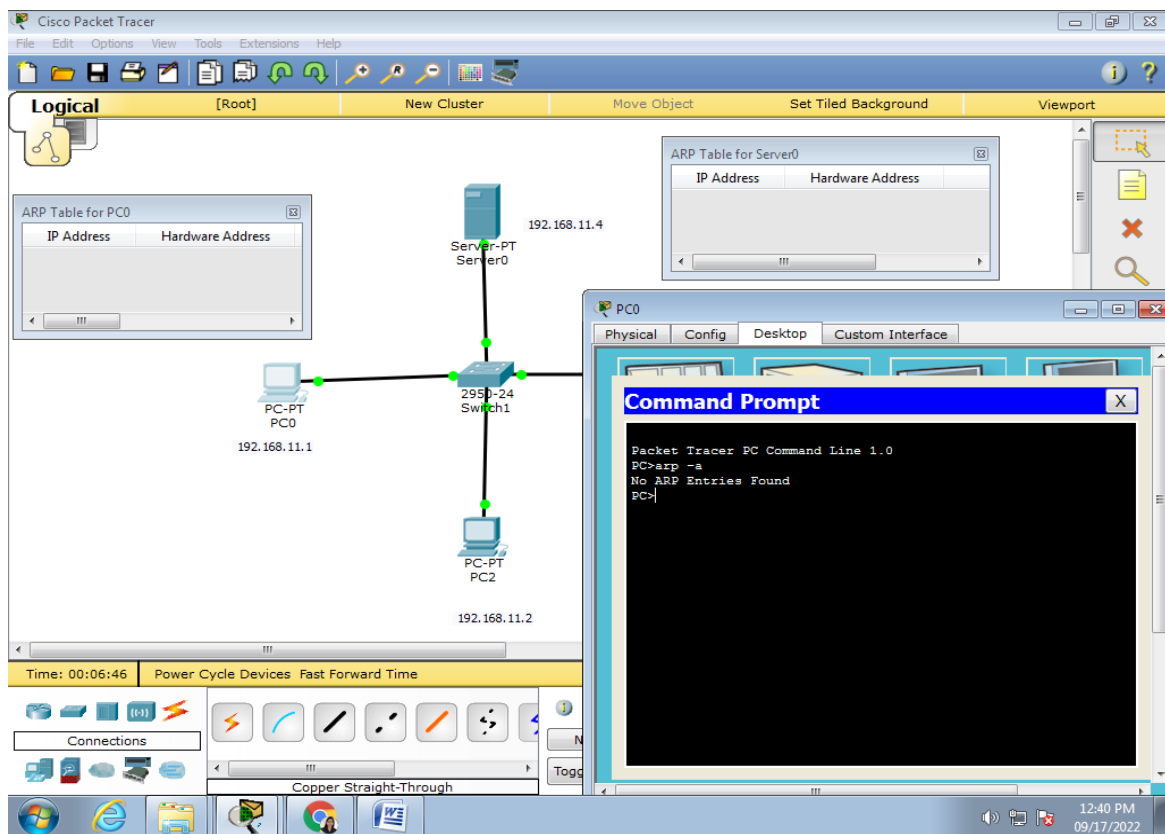

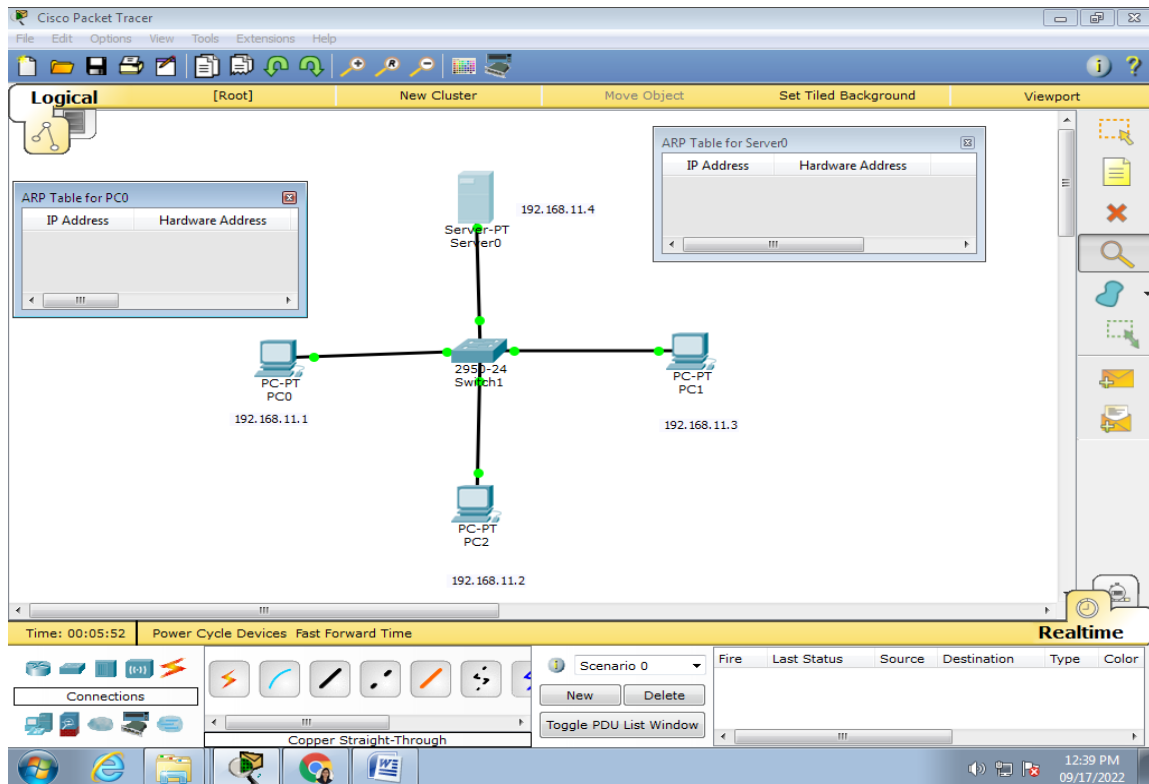

1. Open the software ,cisco packet Tracer student version.
2. Design the network as shown in diagram
3. Configure IP addresses for all pc
4. Check connectivity

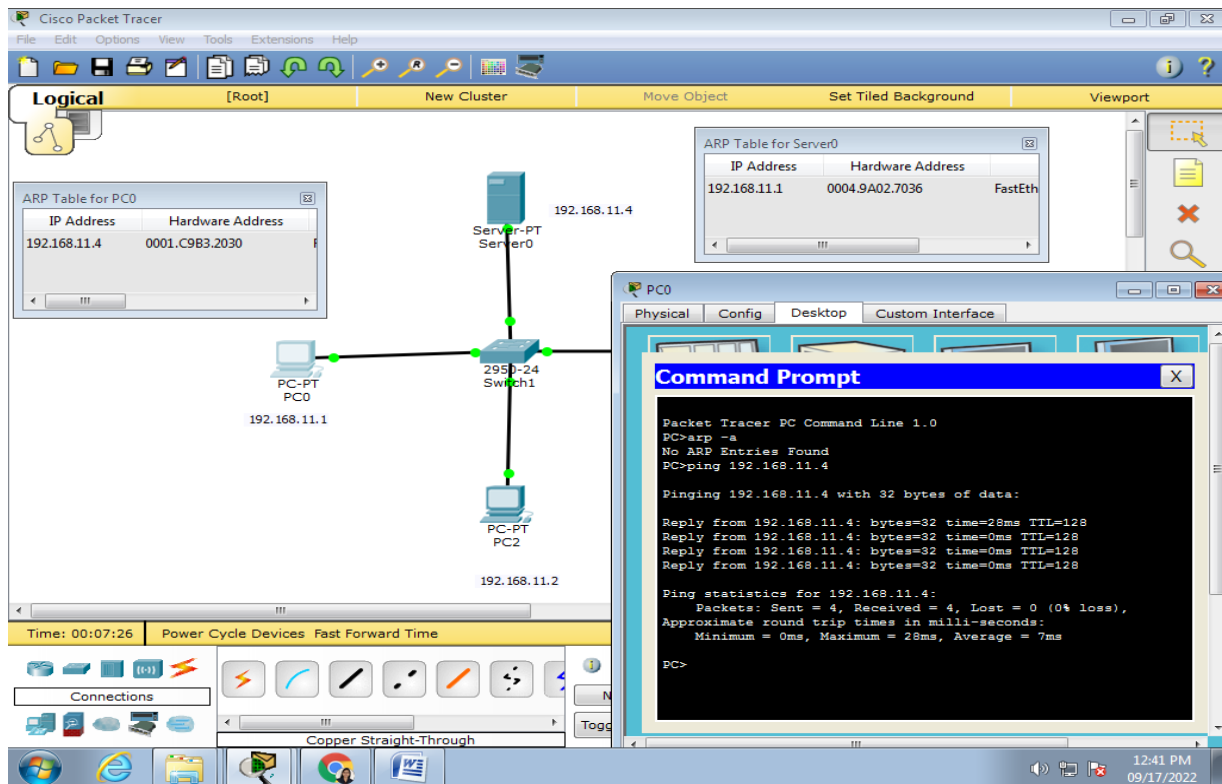

Same for all

5. Click on inspect icon then on PC and right click and open ARP table. Do this for server also
6. Initially in ARP no entry found
7. Click command prompt of source PC
8. `Pc>arp -a.....enter`
9. `PC>Ping 192.168.11.4....enter`

GSMCOE, E&TC

10. Check the simulation

11. Two packets are there one is of ICMP and other is of ARP

12. Click on ARP packet and open outbound PDU for more details

13. Now click on capture / Forward and observe simulation and ARP table

GSMCOE, E&TC

The top screenshot shows a network topology in Cisco Packet Tracer. A central switch (2950-24 Switch1) is connected to a Server-PT (Server1) and three PCs (PC0, PC1, PC2). The IP addresses are: Server1 (192.168.11.4), PC0 (192.168.11.1), PC1 (192.168.11.3), and PC2 (192.168.11.2). Two ARP tables are visible: one for Server1 and one for PC0.

The bottom screenshot shows the 'PDU Information at Device: PC0' window. It displays the details of an ARP request packet. The Ethernet II header shows the destination MAC as 0004.9A02.7036 and the source MAC as 000A.F3DD.03C3. The ARP section shows the source IP as 192.168.11.4 and the target IP as 192.168.11.1.

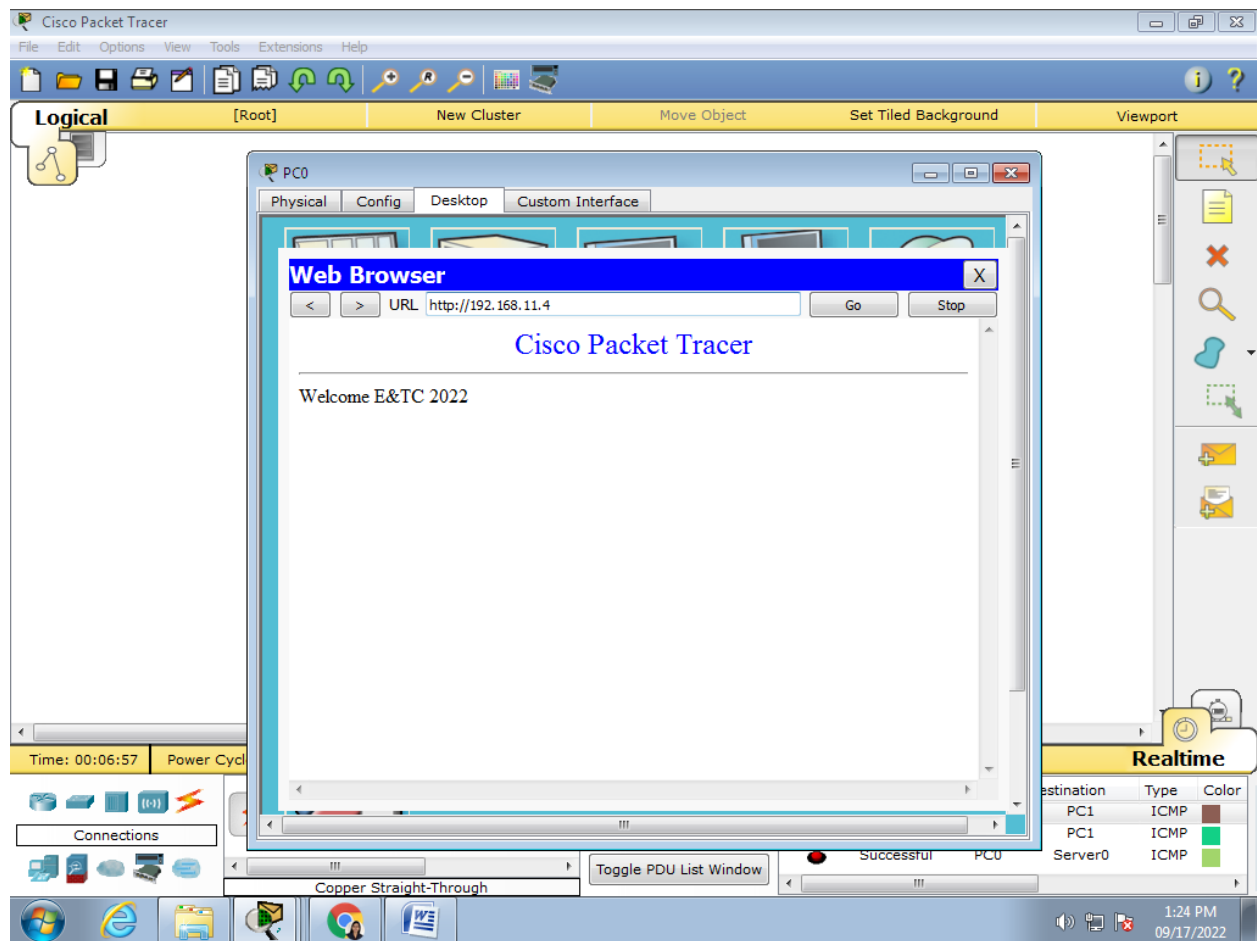

14. Now make server as web server

GSMCOE, E&TC

15. Click on Server and do following setting

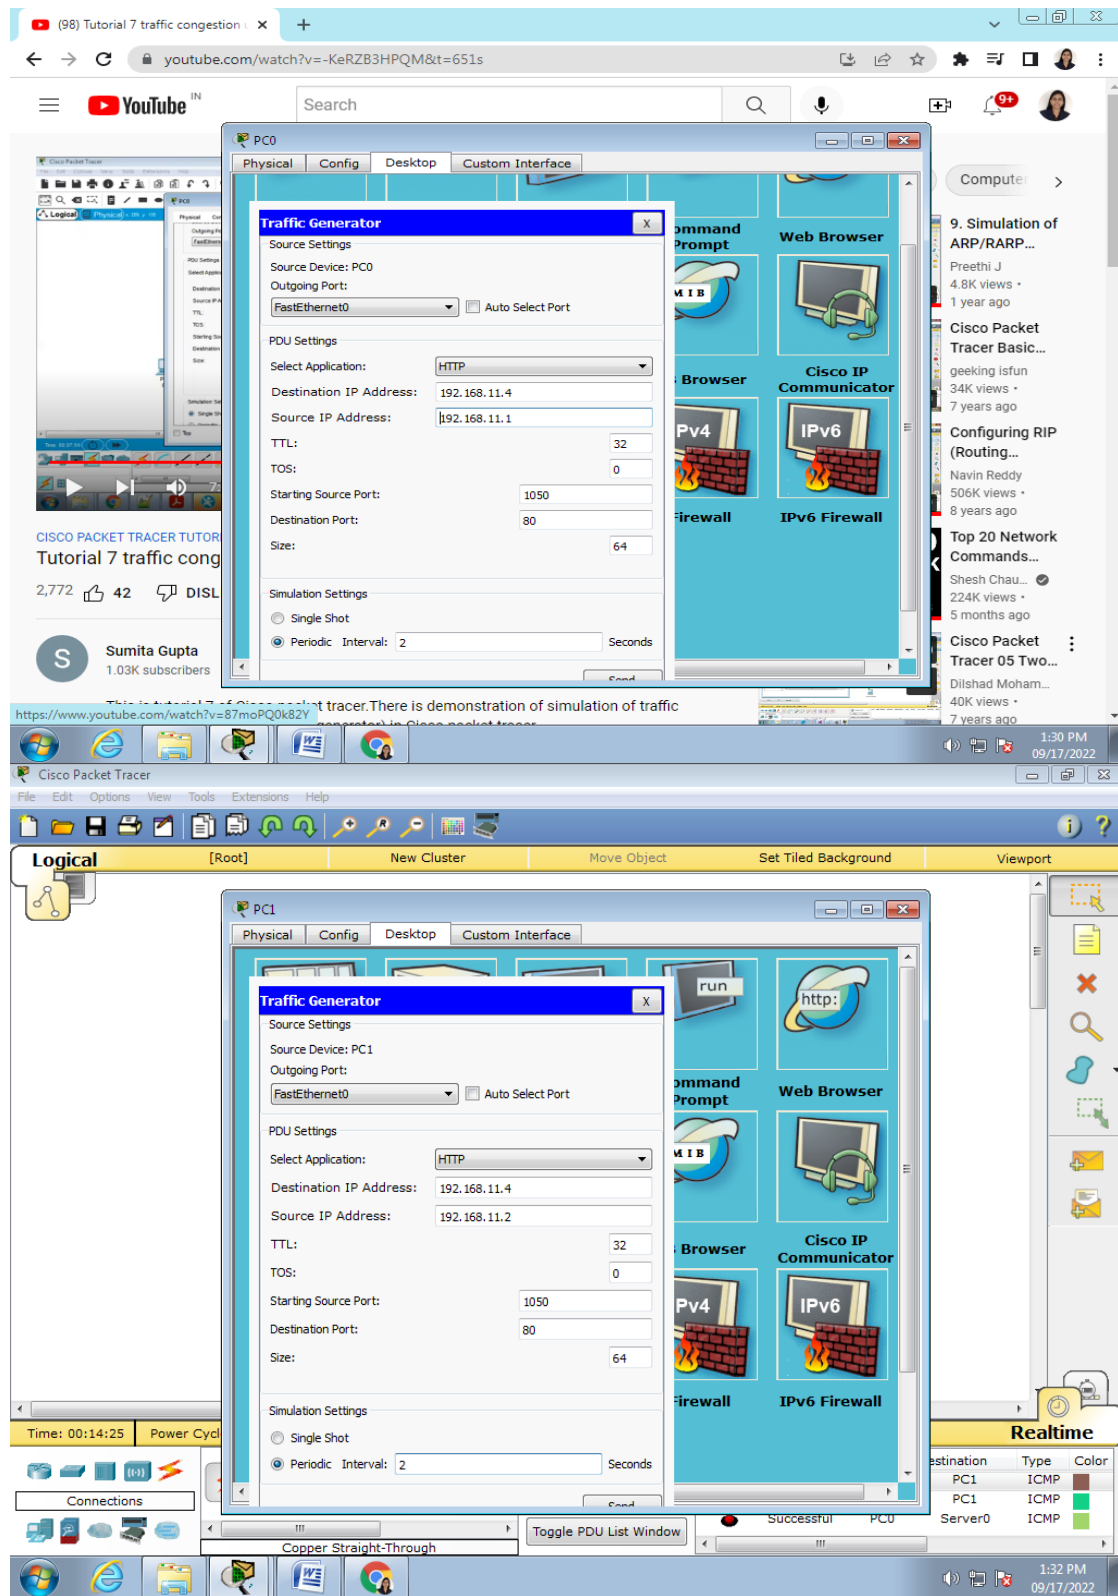

GSMCOE, E&TC

Check for all PC

16.Now Click on PC0 and open traffic generator

Repeat for all PC
